Integrating Supply Management and Financial Data for Predictive Cost Management and Operational Planning

Alimatou Jallow, Mary Jatta, Sarah Cobbinah, Veronica Ibe*, and Toluwalase Ayeni
Received: 11 September 2024/Accepted: 21 December 2024/Published: 31 December 2024

Abstract: *This conceptual paper looks at the bifurcation of supply chain management and corporate finance, which, in the traditional view, led to reactive cost management, operational departments as islands, and supply chain volatility. The study brings together the literature on ERP and real-time telemetry, and extends it with additional concepts for financial ledger sync and a multi-layered system for prediction, which consists of data ingestion, integration and analytics, and operational execution, transferring organisations away from retrospective variance reporting towards proactive cost management within the context of ERP. This illustrates how operational data can be shared with financial planning models, drive working capital efficiency, minimise TCO and help to facilitate decision-making across the CFO and Chief Supply Chain Officer. Further, the implementation challenges like compatibility and data security are discussed alongside future empirical study opportunities and finance settlement opportunities through blockchain.*

Keywords: *Data Fusion, Enterprise Integration, Operational Resilience, Predictive Cost Management, Supply Chain Finance, Working Capital Optimization*.

1.0 Introduction

The need for separation of functions and structures between supply chain management (SCM) and corporate finance (CF), as well as the existence of interfaces between them, has been a hallmark of the modern company for decades (Wetzel & Hofmann, 2019). The procurement and supply chain (PSC) have historically been considered as tactical execution units whose key performance indicators (KPIs) mainly aim to guarantee continuity and volume throughput, that is, providing the right products and materials (Tvedt & Hovi, 2024). On the other hand, corporate finance and treasury departments (CFT) have been dealing in an accounting-controlled domain, and have been mostly engaged in general ledger reconciliation, capital allocation, liquidity management and variance reporting. This was a traditional bifurcation with the presence of separated operational silos, where the physical supply flows were monitored, analyzed, and managed, whereas the financial cash flows (Carnovale, Rogers & Yeniyurt, 2019). There was little, if any, visibility into the corporate capital constraints for supply chain managers, and little if any visibility for the financial controller that spend in procurement would be dynamic rather than a fixed budget line that would vary based on market signals.

This fragmentation is grounded historically and has led to the development of reactive cost controls in the industrial/commercial sector (Moretto *et al*., 2019). This is because purchase structures, enterprise resource planning (ERP) techniques, and economic ledgers operate on batches and use various units of measurement and organizations will only be aware of cost overruns, supplier shocks in price and working capital squeezes, after the fact when the difference shows up in the quarterly balance sheet (Gopal *et al*., 2024). This puts the management teams, with their "crisis management" mentality, into emergency cost cutting, where inventory or supplier relationships are frozen or hastily negotiated – all of which have an adverse effect on enterprise value, as operation planning becomes difficult if not impossible. Most importantly, if there is no information system, both physical information system and financial bookkeeping system, then the decision makers are not aware of the cascading effects on the finances that can arise from production delays, increased material costs, etc. until the financial damage has been issued (Ivanov & Dolgui, 2021).

Today, however, with macroeconomic volatility and geopolitical conflicts and supply chain fragilities unprecedented, it is not possible anymore to take a reactive approach (Katsaliaki *et al*., 2022). Price volatilities in the costs are persistent, and also the difference in different prices of commodities, the sudden change in the foreign exchange market and the change in regulations impact the organizations (Pellegrino *et al*., 2019). These dynamics of the high frequency market are not visible in the traditional budgeting systems and historical cost accounting; thus they cannot be taken into account to create an enterprise plan. The main problem of the current strategic approaches is that they have to fight against the fragility and replace retrospective accounting with prospective resilience and firefighting with cost predictability because of systematic integration of operational and financial intelligence (Baryannis *et al*., 2019).

To address those operational vulnerabilities, the concept of real-time data fusion with a deliberate integration of granular telemetry data from the supply chain and corporate financial ledgers and predictive analytics is key (Song, Li, & Yu, 2021). An integrated data ecosystem (Bals, 2019) can be created through combining real-time procurement data, inventory turnover data, supplier performance data, live cash flow projection data, AP scheduling data and macroeconomic data. This information is combined to support predictive cost management, the simulation of cost trends with machine learning algorithms and advanced econometric models, and the consequences on margins with incoming supply chain disruptions before they even occur (Pournader *et al*., 2021). Data fusion is not a handoff shift between finance and supply management, but a feedback loop; that is, at each operational decision, financial liquidity is verified and in each financial plan, the conditions of the supply market are updated (Riahi *et al*., 2021).

This is a conceptual paper to show how this operational gap can be bridged and to rethink the theory behind operational planning and supply chain finance. The main research objective is the development of the concept of an integrated architecture bringing together the streams of procurement data and financial planning models and thus enabling a proactive control of costs. The paper discusses some of the key research–practice gaps in the management literature from reporting to predictive data fusion in organizations. It examines the integrated data frameworks' potential to improve an organization's working capital, lower Total Cost of Ownership (TCO) (Subiyanto & Asadi, 2023), and further cement the strategic relationship between CFOs and Chief Supply Chain Officers (CSCOs).

Last but not least, this work could be considered as a theoretical contribution in the fields of supply chain finance, operational research and management. This paper proposes a multi-level conceptual framework that explicitly relates the supply signals at the operational level to the outcomes of financial planning and provides a sound foundation for future empirical analyses and organizational change. It helps to shape the conversation on enterprise digitalisation and brings clarity to examples of how enterprise digitalisation in supply management and finance can help businesses become agile, able to plan for the future and resilient in their operations, without just reducing material cost or finding a cheap source of independent credit.

2.0 Theoretical Foundations & Literature Review

Cost management has been developed as a paradigm shift from backward accounting practices towards a forward-looking strategic planning, using data (Nik Abdullah *et al*., 2022). Traditionally, cost control in any organisation has been an after-the-event variance analysis, where the financial controller at the end of a reporting period (typically a month, a quarter or a fiscal year) compares the actual amount spent in his/her organisation's budget with the budgeted amount. This approach provides governance and accountability but is by nature backward-looking. Variances will only be identified after the operational events in the variance have occurred and will only be corrected – management actions will be corrective not preventative. The organizations that are purely retrospective are constantly chasing fires and suffering losses because of margin erosion and inefficiencies in the supply chain, but don't have the structures in place to be searching for – and catching – cost inflation issues.

In contrast, predictive cost management is a forward-looking process that is based on sophisticated analytics, accurate, real-time data, and machine-learning models that help to anticipate cost trends before they are finalized (Uyar, 2021). Predictive cost management is contrasted with post-consumption questions of why a budget was blown by answering the following question: "In what ways will cost structures respond to other operational, market and geopolitical scenarios in the future?" It is a forward-looking approach, which takes the different parameters of procurement and supplier lead time into account; coupled with external macro-economic indicators, it gives the decision makers the ability to look up and assess the impact of finance on procurement decisions in real time. Changing the focus from hindsight to foresight of cost-control provides enterprises with the chance to adjust foreseen orders, renegotiate supplier contracts, prepare for commodity price changes and also manage working capital in advance of actual working capital cost.

This is at the intersection of Supply Chain Finance (SCF) and strong data interoperability between enterprise architectures. Modern supply chain finance (MSCF) was designed to address the financial gap that occurs during each stage of the product's life cycle between the buyer, supplier and financial institution to create better cash flow and liquidity for the supply chain (Zhang, Zhang and Pei, 2019). However, traditional SCF methods such as supplier financing and reverse factoring, even dynamic discounting, have traditionally been limited by fragmented information systems (Kouvelis & Xu, 2021). A standalone procurement system results in fragmented, non-real-time view on order statuses and inventory velocities for financial institutions – an important foundation in order to be able to offer the optimal credit terms or risk-adjusted financing (Chod *et al*., 2020). True data interoperability is the real prerequisite to modern SCF as a result, which means turning SCF from a mere transactional banking tool to an embedded operational strategy.

The first pillar refers to integration with enterprise resource planning (ERP) as the nervous system of data flow integration in the organization (Tarigan, Siagian, & Jie, 2021). However, traditionally those business units would be on their own databases and procurement would be in one language, inventory in another and financial accounts in another and all databases would update at different times – these are data silos. Modern publications focus on the role enterprise integration and/or high-level middleware plays in making sure that several enterprise components communicate, act as one man's source of truth, which is ERP. When integrated in an ERP environment, procurement purchase orders, accounts payable ledgers and inventory management systems are in perfect harmony, giving financial officers a real-time view of committed liabilities. This eliminates latency, streamlines administration and clears, normalizes and synchronizes business data to be used in financial forecasting models.

In procurement and logistics, outside the ERP wall, the IoT (Internet of Things) telemetry has provided a tremendous amount of data and unprecedented speed of data flow for financial analysis (Unhelkar *et al*., 2022). Traditional procurement data was mostly static, comprising PO quantities, negotiated rates and approximate delivery dates. Today, sensors, RFID tracking tags and telematics vehicles deployed across the worldwide supply chain are producing ever finer particles of real-world physical data: where things are and aren't, harsh environments, residency in warehouse, manufacturing throughput, etc. These high-frequency operational metrics are then delivered to enterprise analytics for unprecedented leading indicators of cost. Transit information in real time, for instance, can instantly inform financial planners about potential logistical holding times, congestion in port of working capital implications, and let them calculate the holding costs, expedited freight and other implications days before the delayed goods are received.

The last step of this technological ecosystem is to synchronize the financial ledger with operational events happening on the supply chain to form an uninterrupted, transparent audit and planning trail (Helo & Hao, 2019). Financial ledger synchronization is defined as a process of comparing general ledger accounting transactions with implemented milestones in the operations such as raw material excavation, dispatch confirmation, component manufacturing and quality inspection etc. The notion of distributed databases and the modern ledger architecture enables organizations to implement automated financial reconciliations and dynamic, event-driven financial transactions, like automated invoice processing or making use of early payment discounts that are dependent on real-world delivery, for instance (Raj *et al*., 2022). This eliminates the usual "invoice-to-pay" delays and makes corporate liquidity management in line with the physical velocity of the supply chain.

Table 1: Comparison of Traditional vs. Integrated Predictive Models

Dimension	Traditional Siloed Approach	Integrated Predictive Framework
Data Source	Historical general ledger & delayed invoices PNG	Real-time ERP, supplier telemetry, market indices PNG
Cost Horizon	Retrospective variance reporting PNG	Dynamic, forward-looking cost projections PNG
Planning Cycle	Annual budgeting /	Continuous rolling

	quarterly review PNG	operational planning PNG
Decision Focus	Cost containment after the fact PNG	Proactive mitigation and risk hedging PNG

A predictive modeling approach to optimizing business operations (Balogun et al., 2021)

To conclude, the ERP integration of these literature domains – IoT telemetry, financial ledger synchronization – shines a light in the direction of a single structure for predictive cost management and working plan. Today, with a changing world and an open market, businesses with only low costs in their physical supply chain and in corporate finance are not competitive, as the academic and industrial world clearly shows. Instead, organizational resiliency and, ultimately, more cost-effective workflows flow from discarding the concept of data silos and establishing a digital network where the flow of goods and the flow of money are integrated and can be tracked, managed and optimized as a single process.

3.0 Proposed Conceptual Framework & Architecture

To make the convergence of SCM and corporate finance more operational, in this conceptual paper, a solid, three-layered framework was put forward: Data Ingestion Layer, Analytics Engine, and Operational Execution Layer (Song, Li, & Yu, 2021; Yu *et al*., 2021). The first tier is Data Ingestion, which is responsible for the 'sensory system of the enterprise' to ingest and normalize data from the various data sources as 'disparate data streams' (Agrawal *et al*., 2022; Ben-Daya, Hassini & Bahroun, 2019). This includes all internal ERP transactional data, accounts payable and receivable ledgers, real-time telemetry data of IoT supply chain and external macro-economic data like commodity price indexes, foreign exchange rates (de Vass, Shee & Miah, 2021). This tier removes latency in leveraging historical data and data structuring walls and ensures that data around more real-time operational aspects and financial obligations is constantly pushed to a clean and centralized data repository (Dolgui & Ivanov, 2022).

The second tier of the overall framework is the Analytics Engine, which is the "cognitive centerpiece" of the overall framework and is responsible for advanced data fusion and predictive modeling (Feizabadi, 2022) on this synchronized data foundation. This Analytics Engine can be used to identify future cost profiles by analysing trends and combining live data feeds, to simulate identified areas of working capital security and potential bottlenecks in the supply chain, with machine learning algorithms and time series forecasting and econometric simulation. This engine can provide forward-looking estimates of margin erosion prior to its occurrence, by taking forward-looking estimates based on operational data such as transit delays or the shifting price of raw materials.

The last level is Operational Execution, and the strategy and finance derived from the prediction-based approach offer a means of making proactive moves in the enterprise and for automating the processes, completing a full circle from strategic finance to operational day-to-day procurement processes (Abdulla & Baryannis, 2024). Potential areas for spend growth or cash flow shortage are automatically identified by the Analytics Engine and translated into the execution tier, by means of supplier hedges, flexible supplier order scheduling, renegotiated supplier order terms and reallocation of working capital every pre-defined (or AI-recommended) period. Additionally, the feedback from the outcomes of decisions made at the operational level can assist the system in further enhancing the accuracy of its predictions and enhance its

agility and cost resilience in the long term (Wu *et al*., 2024).

The core of the proposed architecture is the high-level predictive costing mechanisms, which make use of the machine learning algorithms that analyse the rich multidimensional data coming from the ingestion and analytics layers (Zhu *et al*., 2019). Traditional cost forecasting models are largely static and have been formulated based on linear regressions or moving average formulation, and they easily fail to capture this intricacy and non-linearity of the interdependencies between the disturbances in the global supply chain and the financial exposure of the companies (Foroutan & Lahmiri, 2024). Advanced machine learning models like gradient boosting machines, random forests, and recurrent neural networks (RNNs), on the other hand, can naturally process and relate to various streams of data with high frequency (Foroutan & Lahmiri, 2024). These algorithms, however, consider the historical general ledger bookings, real-time shipment telemetry data, supplier performance histories, and real-life macroeconomic indicators as a whole, creating dynamic predictive models that reveal hidden causal patterns of the cost behavior (Ben-Daya, Hassini & Bahroun, 2019).

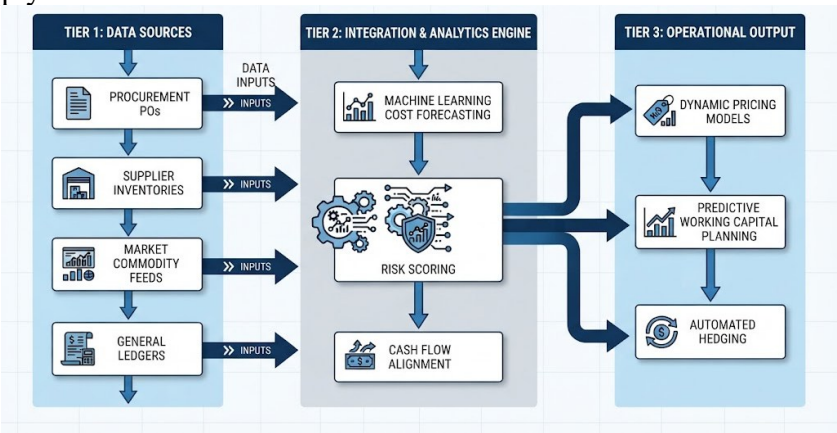

Fig. 1 End-to-End Data Flow for Supply-Finance Integration (Mohammed & Mandal, 2024)

When applied to price forecasting, they can enable predictive mechanisms that forecast the price evolution and volatility in raw material procurement costs well before the purchase order is placed (Markou & Corsten, 2021). Enterprises can continuously monitor fluctuations in external commodity indices, geopolitical risk scores, supplier production limits, historical data, etc., and speculate on the inflation trend or market dip and decline (Abdulla & Baryannis, 2024; Wu, 2024). For instance, the landed costs can be accurately predicted by the algorithm by analyzing real-time operating data of the suppliers and financial settlement conditions and currency exchange rate fluctuations (Huang, Chan, & Chung, 2022; Pfahler, 2022). This foresight helps the procurement teams and financial controllers to shift from reactive purchasing to proactive strategic sourcing, e.g., procuring ahead of time to avoid price hikes or aligning the purchases with the most liquid working capital (Song, Li, & Yu, 2021).

Beyond the cost of raw materials, in the case of different lead times it is also crucial to try to quantify the financial impact, which is where the idea of predictive cost mechanisms comes into the picture (Barros, Cortez & Carvalho, 2021; Wu *et al*., 2024). Hidden costs of supply chain bottlenecks are only evident when ledger-reconciliation processes are part of the traditional accounting system (Markou & Corsten, 2021) due to port congestion, manufacturing delays or logistic issues.

Machine learning models fill in this gap by directly mapping physical deviations in lead time onto financial measures, calculating in real time the financial costs of holding safety stock, paying for emergency freight charges and losing out on potential stockout penalties (Barros, Cortez & Carvalho, 2021). The analytics engine works with corporate accounts payable and cash flow schedules to give decision-makers a comprehensive, forward-looking view of the value of operational risks and solidify the connection between supply chain execution and financial planning (Yu *et al*., 2021).

4.0 Managerial Implications & Operational Impact

The Chief Financial Officer (CFO) and Chief Supply Chain Officer (CSCO) have always been on the opposite sides of a functional chasm due to their separation in traditional corporate governance (Emtehani, Nahavandi, & Mokhatab Rafiei, 2021; Wetzel & Hofmann, 2019). The CSCO's objectives used to be related to the physical throughput and the availability of inventories, to the reliability of suppliers and the speed of operations (Toušek *et al*., 2022), and the goals of the CFO to the preservation of capital and reduction of costs. This can lead to strategic friction, where finance cuts costs ever more aggressively, depriving supply chains of free cash flow and capital to develop suppliers, and where supply chains demand high volumes of inventories, thereby reducing corporate liquidity (Hofmann *et al*., 2022; Kajjoune *et al*., 2023). The strategic connection between these two key pillars of the executive role eliminates the disconnect between the two and transforms procurement into a working capital optimization (WCO) enabler – according to Chen & Archibald (2024) and Yoo, Choi & Kim (2021).

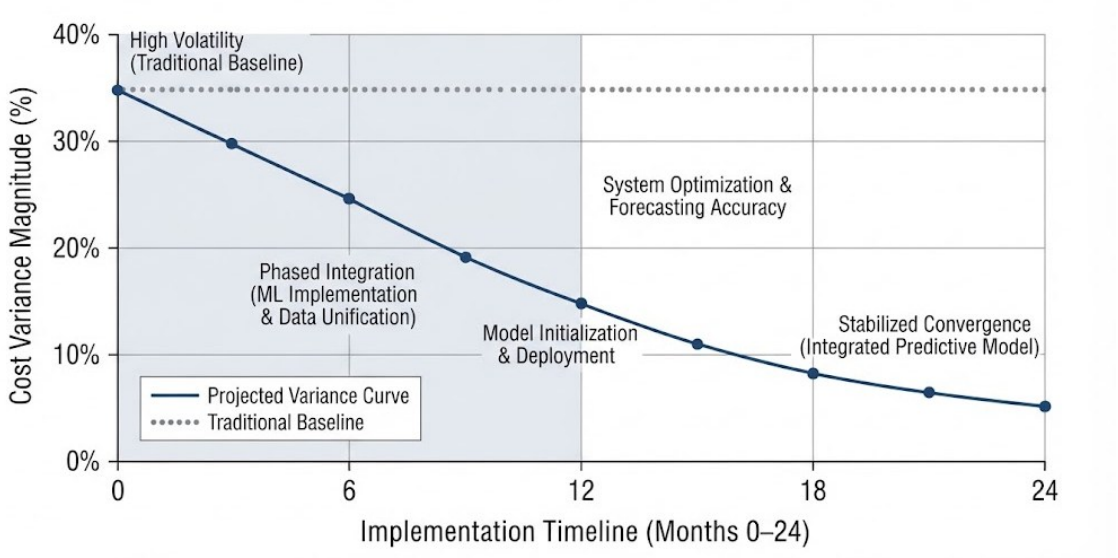

Fig. 2 Projected Cost Variance Reduction Over Time (Polo-Triana, Gutierrez & Leon-Becerra, 2024)

When liquidity management is shared and predictive data ecosystems are in place between CFOs and CSCOs, this active collaboration is able to change the way liquidity management works (Song, Li, & Yu, 2021; Onyijen et al., 2023). Both executives can see how their physical supply chain decisions affect finances — without having to separately track accounts payable and accounts receivable to calculate cash conversion cycles. Predictive

cost analytics can be incorporated into working capital planning, for instance, to fine-tune inventory holding strategies while maintaining liquidity (Chen & Archibald, 2024; Emtehani, Nahavandi, & Mokhatab Rafiei, 2021). Suppliers can be onboarded onto platforms with dynamic discounting or a supply chain finance model, and payable float can be extended for the buyer, while early liquidity for critical Tier 1 and Tier 2 suppliers is provided based on transparent and verified milestones of their operations, such as an automated invoice approval once the goods are delivered and have been confirmed by the IoT sensor.

Lastly, the interaction of the functions directly affects the company's profitability as this will lead to a change in the free cash flow (Toušek *et al*., 2022; Wetzel & Hofmann, 2019). As soon as the financial liquidity requirements are directly modelled into the procurement planning algorithms, purchasing actions are no longer taken blindly based on the departmental budget (Kajjoune *et al*., 2023; Chen & Archibald, 2024). Instead, procurement strategies are dynamically adapted to the cash flow forecasts, and future investments in inventory and SC hedges (Markou & Corsten, 2021; Wu *et al*., 2024) are taken into consideration in the treasury management. This holistic strategy can help avoid working capital problems, reduce capital costs, and equip the company to safely navigate macroeconomic uncertainty with seamless financial agility and operational resilience (Hofmann *et al*., 2022; Wu *et al*., 2024).

Table 2: Operational Impact Matrix Across Enterprise Functions

Enterprise Function	Key Integration Metric	Operational Benefit
Procurement	Total Cost of Ownership (TCO)	Optimized supplier contract terms aligned with cash flow cycles
Finance	Working Capital Efficiency	Accurate liquidity forecasting and reduced buffer capital requirements
Operations	Production Scheduling Cost	Minimized stockout costs and optimized inventory holding levels

Predictive analytics models for SMEs to forecast market trends, customer behavior, and potential business risks (Ugbebor, Adeteye & Ugbebor, 2024)

Enterprise profit margins are also related to their defense against unpredictable shocks, such as geopolitical friction and macroeconomic fluctuations, and predictive cost visibility is an integral part of this defense (Ivanov & Dolgui, 2020). But this is also the time of unforeseen trade tax hikes, export bans, currency depreciations and regional wars, and reactive cost management can leave companies with a serious margin reduction due to unexpected costs on the balance sheet coming out of thin air (Queiroz *et al*., 2022). Predictive analytics can take real-time data from SC sensors and also macroeconomic data to predict potential disruptive events, such as shortages of raw materials or increases in transportation costs, weeks or months ahead of time—before they actually occur (Baryannis *et al*., 2019; Ivanov & Dolgui, 2021). This early-warning capability allows risk managers and procurement strategists to take proactive measures to avoid risk and mitigate it, including diversifying their supply chains, incorporating stable geographies with reliable suppliers, currency-hedge contracts or dynamically rerouting logistics before any

major bottlenecks arise that fuel up the spot-market pricing (Dolgui & Ivanov, 2022; Gurtu & Johny, 2021). Predictive cost visibility, therefore, transforms risk management from a reactive compliance practice into a proactive and smart defense to ensure business continuity and healthy profit margins through a worldwide tempest (Ivanov, 2022).

5.0 Conclusion

Lastly, this conceptual work acknowledges that supply and financial data need to be combined as imperative enablers of organizational strategic agility. The framework provides a way to consolidate the relevant concepts and theories and demonstrates why and how crossing the functional lines can enable companies to transform disjointed streams of data into proactive insight. When combined with real-time financial ledgers and accounting, procurement and logistics operational telemetry can replace the need for variance reporting and replace it with predictive cost management. These integrations allow leadership to plan their operations dynamically, phase the cash conversion cycles with the supply velocity of the physicals and make agile plans which will be a clear competitive advantage and a possible cost burden.

Even if the benefits of predictive cost structures are clear, there are major issues in implementing these that can be a barrier to adoption. One of the most important of these is the pervasive data transparency and security challenges associated with data breaches and the disclosure of intellectual property when businesses do so much more sharing of information regarding their operations and bottom lines, all the way down the supply chain. Also, legacy system compatibility can be a big technical hurdle, since there are many businesses out there that are using legacy systems, such as incompatible enterprise resource planning (ERP) modules, or data silos which do not easily accept a seamless integration piece of software known as middleware. In addition to these technical and security constraints, there is also an organizational constraint: the culture of silo thinking and the organizational distances between the risk-averse finance departments and the volume-driven procurement units can make processes come together difficult.

Resolution of these important gaps and validation of the proposed conceptual architecture provide important avenues for future research and empirical investigations. Future research should move from the conceptual modelling towards longitudinal and empirical studies in different areas of industry in order to quantify the actual impact of predictive data fusion on the improvement of the working capital efficiency and the stabilization of the profit margin. In addition, new solutions to data security problems and opportunities to build smart contract systems and distributed ledgers for the financial settlements in multi-tiered supply chains with the support of blockchain or any other future decentralization technologies should be explored, guaranteeing authorization and tamper-proofing. In practice, these implementation-focused and scalable enterprise tests will help bridge the gap between the theory and practice of enterprise SCF.

To conclude, the traditional antagonism between corporate finance and supply chain management has now become a key and preliminary concern for corporate life and development nowadays. As the world becomes more volatile in a geopolitical and macro-economic sense, the margin erosion and lack of strategic move on the cost management front will be inevitable for companies that are still stuck in the age of cost management as a reactive, “silo mentality”. On the other hand, organizations can establish an indestructible connection between financial liquidity and

supply chain resilience with the multi-tiered data fusion architecture proposed in this paper. That complete integration translates into intelligence at the time of the decision, not afterwards, and is predictive intelligence that can confidently weather the storms of tomorrow's global economy.

Availability of Data and Materials

. The publisher reserves the right to make the data publicly available in accordance with the journal's data-sharing policy.

Competing Interests

The authors declare that they have no competing interests or conflicts of interest.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Authors' Contributions

Alimatou Jallow led conceptualization, methodology, and original draft preparation. Mary Jatta and Sarah Cobbinah conducted literature synthesis, ERP and telemetry framework integration, and structural editing. Veronica Ibe developed the predictive financial modeling, working capital analysis, and CFO–CSCO alignment sections. Toluwalase Ayeni contributed economic validation, implementation risk evaluation, and final manuscript review. All authors approved the final version.
